

Axel Meyer, Ph.D.

Professor für Zoologie und Evolutionsbiologie

Universität Konstanz

Born in 1960 in Mölln, Germany
Studied Zoology and Biochemistry at the University of California, Berkeley,
Organismal and Evolutionary Biology at Harvard University, and Biology at the
University of Miami, and at the Universities of Kiel and Marburg

Artbildung und Diversifikation in der adaptiven Radiation von Buntbarschen

Charles Darwin recognized that new species can originate in several different kinds of geographic settings, including "allopatry" (from the Greek *allos* meaning "other" and *patra* meaning "fatherland"), where novel species arise resulting from geographical isolation and lack of homogenizing gene flow, as well as through "sympatric speciation" (from the Greek *sym* for "the same"), whereby populations diverge into separate species even in the absence of geographical isolation. However, the feasibility and frequency of the latter mechanism has been hotly debated ever since Darwin. Although theoretical as well as empirical evidence has been put forth regularly since the 1930s, biological assumptions of models and the level of support of empirical evidence in studies reporting on sympatric speciation are still often doubted, and, even today, few cases are widely accepted as bona fide evidence for sympatric speciation. While examples of sympatric speciation are published quite regularly, although rather infrequently, and rules for testing allopatric speciation are well-accepted, those for sympatric speciation remain controversial.

It is necessary to better understand the limitations of empirical work in determining crucial parameters of theoretical models such as the strength of selection in disruptive selection that is deemed necessary for sympatric speciation to occur. There is an obvious need for communication between theoretical and empirical evolutionary biologists interested in speciation.
